## Motivation

### Diamond as future material for the tracking detectors of the LHC:

- innermost layers → highest radiation damage
- current detector designed to withstand  $250 \text{ fb}^{-1}$  of integrated luminosity
  - ▶ High-Luminosity LHC: replace detector every 12 month
- → look for more radiation hard detector designs and/or materials

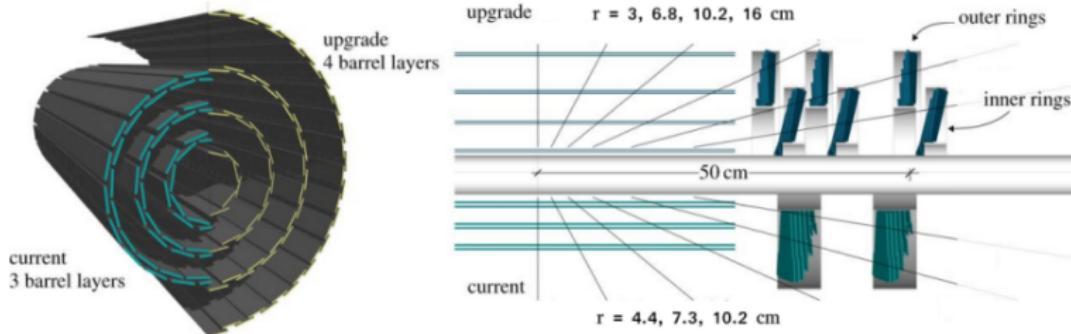

Figure: CMS Barrel Pixel Detector upgrade with end caps

## Section 2

### Diamond Detectors and Materials

## Diamond as detector material

### Diamond as detector material

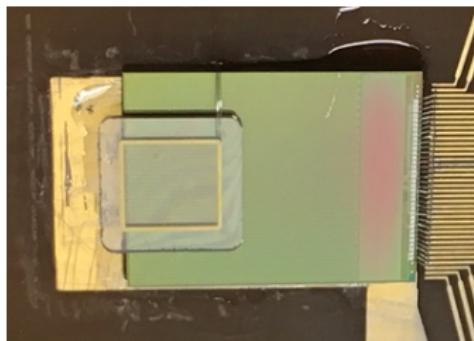

- 7 – 10 times smaller charge loss due to radiation damage than in silicon
- signals (electrons created by a charged particle) half the size of silicon
- → diamond becomes superior than silicon at a certain irradiation
- other advantageous properties:
  - ▶ isolating material → negligible leakage current → power saving
  - ▶ high thermal conductivity → heat spreader for electronics
  - ▶ large band gap → no cooling required
  - ▶ high charge carrier mobility → fast signals
  - ▶ working principle like a solid state ionisation chamber → no pn-junction required
- disadvantages:
  - ▶ high price
  - ▶ some not fully understood behaviours

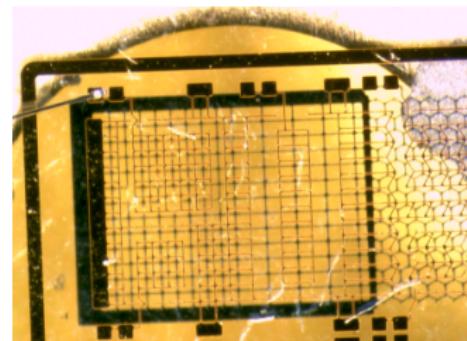

## Detector designs

## Detector designs

- Investigation of two different detector designs
  - ▶ planar diamonds
    - ★ exchange of material
  - ▶ 3D diamonds
    - ★ new type of detector

(a) on CMS-Pixel chip

(b) multi pattern

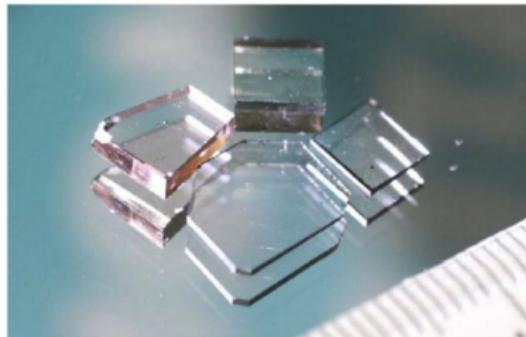

Figure: 3D diamond detectors

## Artificial diamond types

### Artificial diamond types

- used diamonds artificially grown with a chemical vapor deposition (CVD) process
- investigation of two different diamond types:

(a) single-crystalline CVD

(b) poly-crystalline CVD

- grown on existing diamond crystal
- only small sizes ( $\sim 0.25 \text{ cm}^2$ )
- larger signals than pCVD (5 : 3)

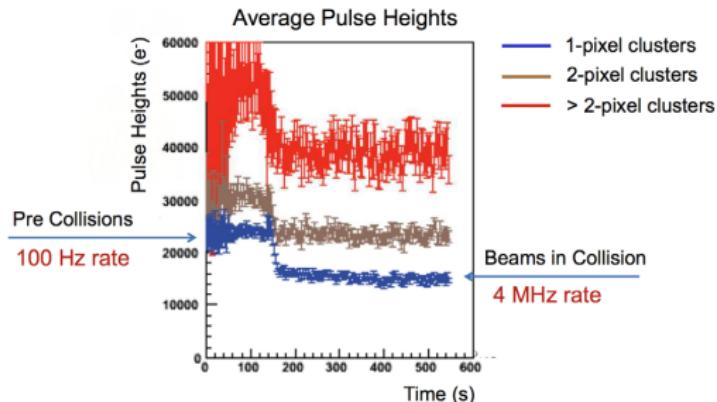

- grown on Si substrate with diamond powder
- large wafers (5" to 6"  $\varnothing$ )
- non-uniformities and grains

Artificial diamond types

## Diamonds in CMS

- scCVD diamond pixel detector used in Pixel Luminosity Telescope (PLT)
  - ▶ goal: stand-alone luminosity monitor for CMS
- observation of a signal dependence on incident particle rate:

### Consequences:

- investigation of the rate effect in scCVD diamonds
- using pCVD diamond and prove that they show no rate dependence

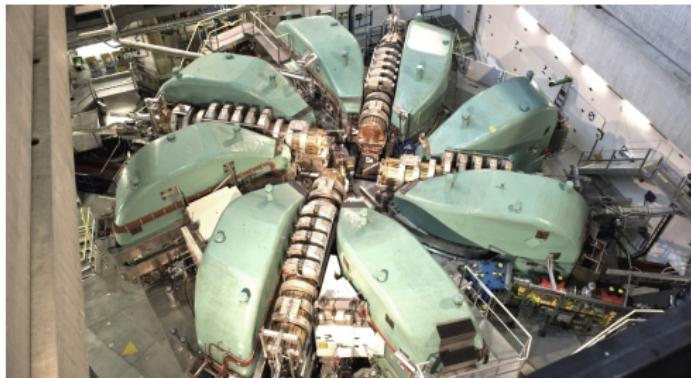

## Section 3

### Rate Studies at PSI

## General information

## Proton Accelerator at Paul Scherrer Institute (PSI)

- High Intensity Proton Accelerator (HIPA) at PSI (Cyclotron)
- 590 MeV proton beam with beam current up to 2.4 mA
  - ▶ ~1.4 MW → most powerful proton accelerator in the world
- only two comparable accelerators
  - ▶ TRIUMF in Vancouver (~0.25 MW)
  - ▶ LAMPF in Los Alamos (~0.8 MW)
- LHC takes 28 min to accelerate a full injection (~0.2 MW)

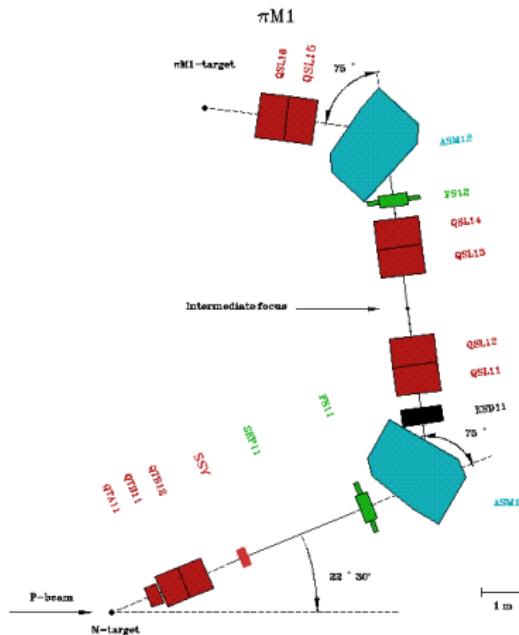

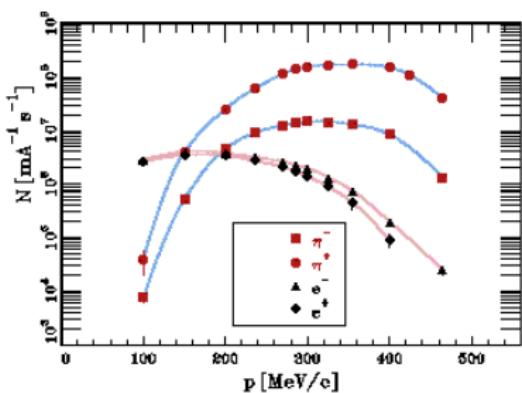

○  
○  
○○

## General information

## Beam line at Paul Scherrer Institute (PSI)

- using beam line  $\pi M1$  with 260 MeV/c positive pions ( $\pi^+$ )
- tunable particle fluxes from  $2 \text{ kHz/cm}^2$  to  $10 \text{ MHz/cm}^2$

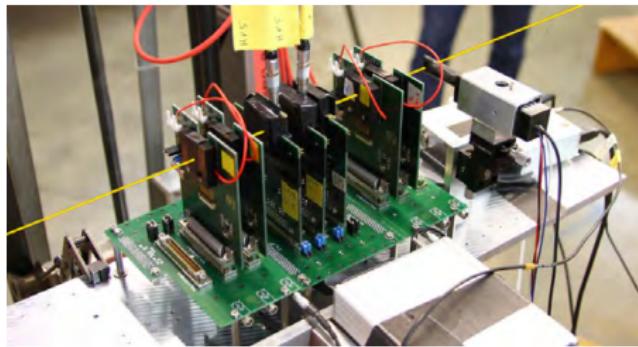

## General information

## Measurements

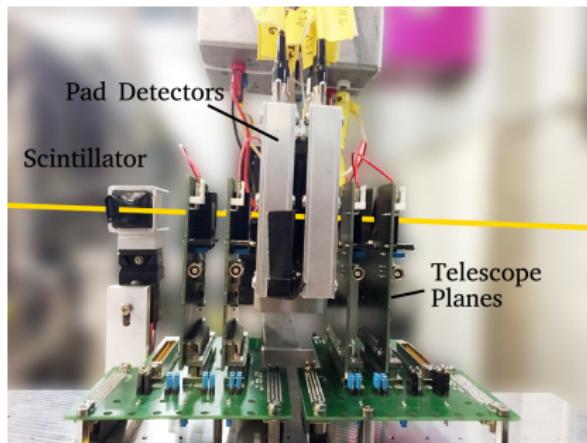

- performing several beam tests starting in 2013
- using a modular self-built beam telescope with two possible setups:
  - ▶ pad setup (testing whole diamonds as single pad detector)
  - ▶ pixel setup (testing diamond sensors implanted on CMS-Pixel Chips)
- investigating several materials and devices
  - ▶ scCVD pad detectors (reproduce rate effect)
  - ▶ pCVD pad and pixel detectors
  - ▶ very first 3D pixel detector
- studying non-irradiated and irradiated devices (up to  $1 \times 10^{16}$  neq/cm $^2$ )

## Setup

# Setup

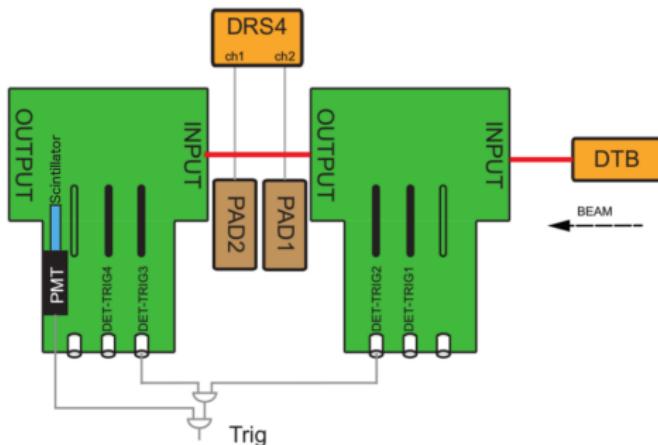

- 4 tracking planes with analogue CMS pixel chips → provide scalable trigger
- 2 diamond pad detectors
- scintillator for precise trigger timing: sigma of 1.3(1) ns
- resolution:  $\sim 80 \mu\text{m} \times 50 \mu\text{m}$

## Setup

## Schematics

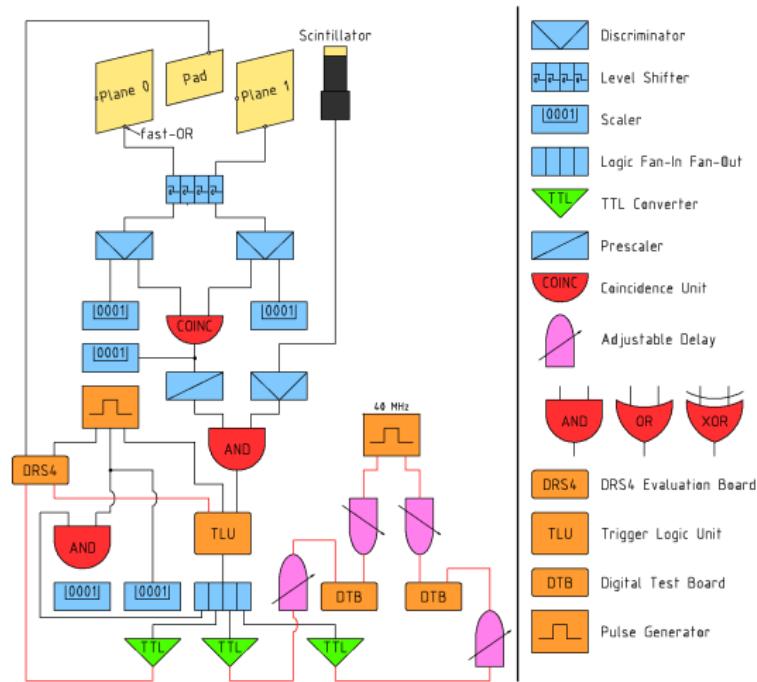

- using PSI DRS4 Evaluation Board as digitizer for the pad waveforms
- using Digital Test Board (DTB) and pXar software for the telescope readout
- global trigger as coincidence of fastOR self trigger and scintillator signal
- EUDAQ as DAQ framework

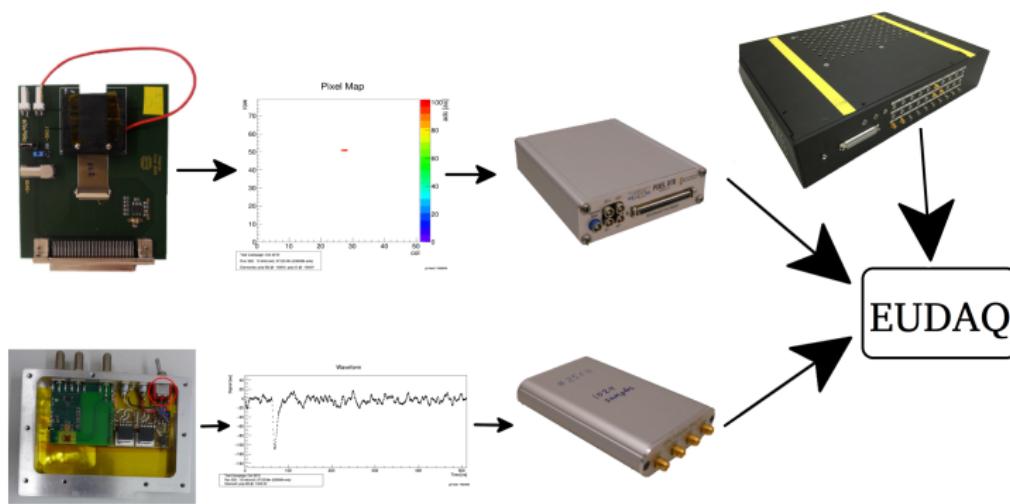

## Setup

## Trigger Logic

- complicated trigger logic
- long setup time
- error prone
- varying cable length

# DAQ

- trigger unit to provide global trigger for all devices
- saving event based data stream as binary file using EUDAQ

## Setup

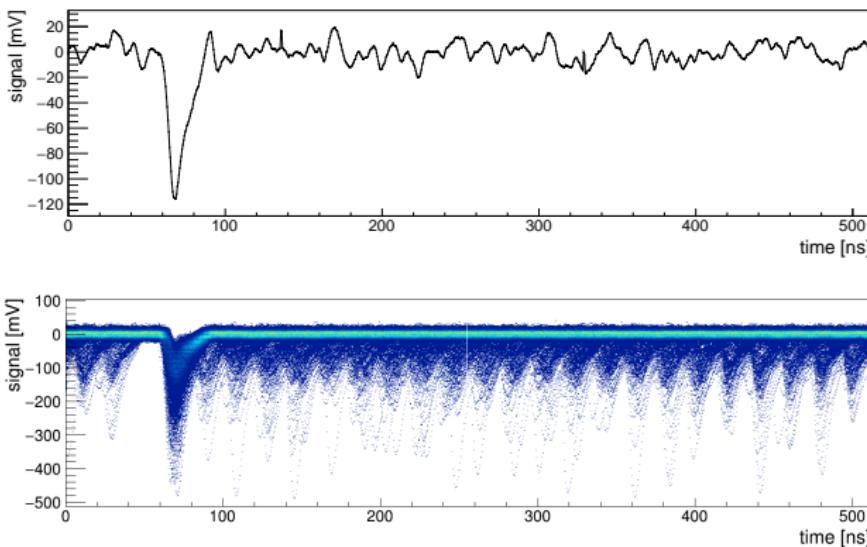

## Trigger unit (TU)

- handles (almost) all trigger logic of the setup with VHDL based FPGA system
- offers scalers for the input triggers, pad signals and beam current
- internal pulser as reference signal
- pre-scalers to guarantee stable pulser rates
- coincidence and handshake logic

## Analysis

## Waveforms

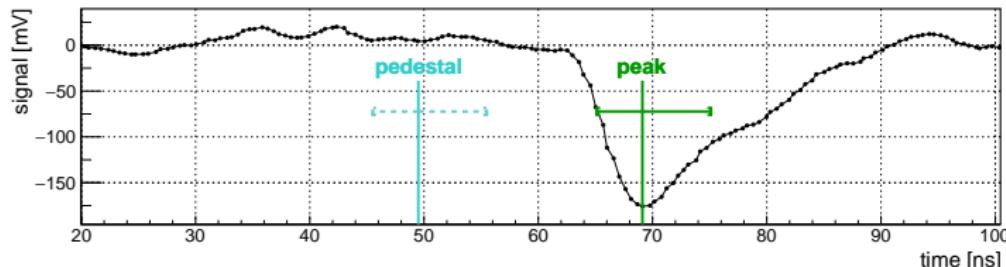

- most frequented peak ( $\sim 70$  ns): triggered signal
- other peaks originate from other buckets ( $\rightarrow$  resolve beam structure of  $\approx 19.7$  ns)
- system does not allow signals in pre-signal bucket due to fastOR trigger deadtime

## Analysis

## Pulse Height Calculation

- finding the peak in the signal region
- integrating the signal in time fixed asymmetric integral around peak
- time averaging
- same procedure for pedestal (base line → noise)
- optimising the integral width by highest SNR (Integral / Pedestal Sigma)
- subtracting the pedestal from the signal integral on event-wise basis

## Analysis

## Event based cuts

(a) no cuts

(b) all cuts

- many undesirable events in the full data (no signal, pulser, multiple hits, ...)
- apply cuts to select only signal events (diamond hit by a single pion)

## Results

## Pulse Height Distribution and Signal Maps

(a) single-crystalline

(b) poly-crystalline

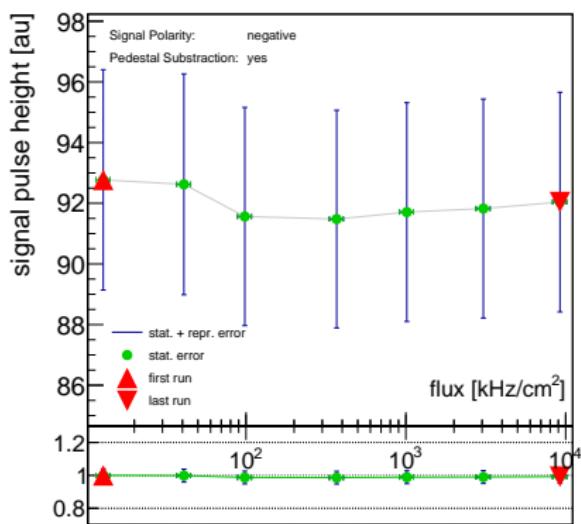

## Results

## Signal vs. Particle Flux

- after all analysis steps: look for rate dependence of pCVD diamonds
- found diamond pad detectors that show no or very little dependence on rate
- no dependence up to  $1 \times 10^{16}$  neq/cm<sup>2</sup>
- large systematic errors due to reproducibility

## To do:

- test higher irradiated samples
- improve reproducibility
- prove the same for pixel detectors

## Section 4

### 3D Detectors at CERN

## Working Principle of a 3D Detector

- insert electrodes perpendicular to the plane
  - ▶ reduce drift distance
  - ▶ increase collected charge in detectors with limited mean free path
- one readout electrode surrounded by four bias electrodes
- in diamond electrodes formed with a pulsed laser
  - ▶ transition of diamond to conducting material (graphitic material i.a.)

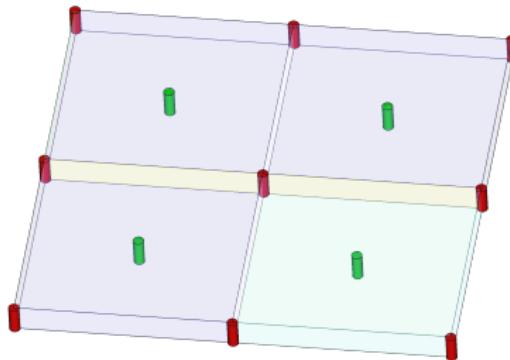

Figure: array of four 3D cells, bias electrodes in red, readout electrodes in green

## Beam Tests at CERN

### Beam Tests at CERN

- using more than 20 years old fixed telescope at SPS at CERN (high spatial resolution)
- testing multiple 3D strip detectors
- basic working principle has been proven
- full charge collection not yet reached in pCVD
- improve fabrication technique

Figure: Strasbourg Telescope

## Conclusion

- High Luminosity LHC requires a new detector technology due to the highly increased radiation damage
- diamond detector designs viable option due to its radiation tolerance, among other advantages
- scCVD diamonds not suitable due to signal dependence on particle flux after irradiation
- pCVD diamonds show no rate dependence up to fluxes of  $10 \text{ MHz}/\text{cm}^2$  and irradiations up to  $1 \times 10^{16} \text{ neq}/\text{cm}^2$
- successfully proven the working principle of a 3D diamond detector
- tested the very first 3D-Pixel detector

### Ultimate Goal:

- build fully working pixel detector
